# Effects of Image Quality, Pixel Scale, and Camera Pose on OCR Accuracy

- What resolution do we require in order for OCR to be robust?
- What are the image processing steps that will help prepare imagery into an optimal form?

OCR candidates being tested: Tesseract & Ocropus

- Provide command line interface that is easy to integrate with prototyping scripts
- Provide API for incorporation into performance-driven implementations of the pipeline as it matures (if necessary)
- Modular design enables range of customization paths

# Effect of Pixel Scale

# OCR

- Size matters – each OCR package seems to have a preferred size for characters
- Characters resized might need post-processing (e.g. smoothing) to successfully be read
- OCR is sensitive to the orientation of text (experiments not shown)

 Implications for labels: need carefully aligned and re-sized image of text for each label

# Obtaining an OCR-ready image

- Positioning of Camera(s)
  - multiple labels in one image
  - high quality image of all labels
    - minimize perspective distortion
    - characters scaled for successful OCR
- Image processing
  - Clean up
  - Alignment
  - Composite image from multiple views

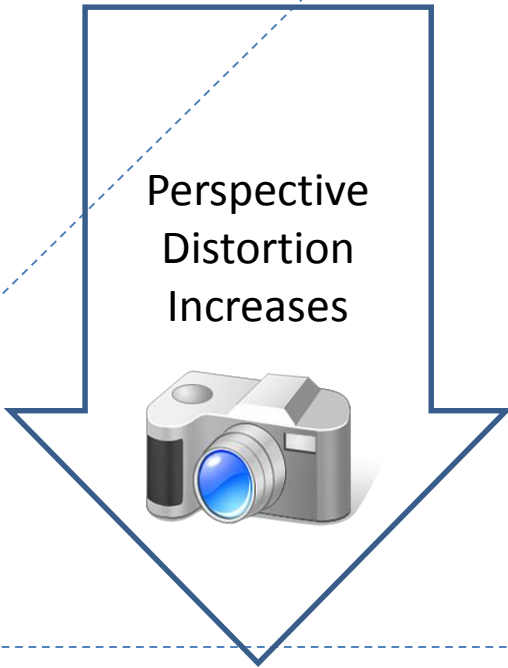

Can't see lower label from viewpoints above the line

Can't see upper label from viewpoints below this line

## Camera Positioning :

we can mathematically model the size/distortion of the characters as a function of the camera optics (focal length, pixel scaling) and the camera pose (distance and orientation)

$w =$  width of label in image pixels

“goal”

$k_x =$  optics parameters (f, scaling)

$\ell =$  label dimension

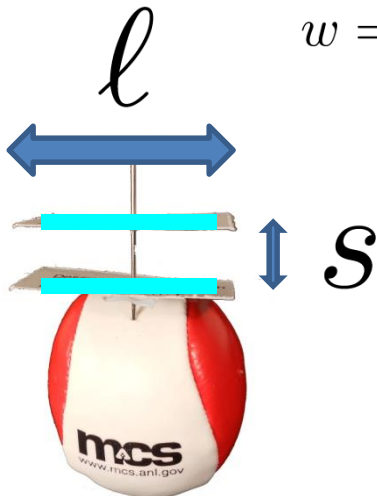

“fixed”

$d_x, d_z =$  camera position

$\phi =$  camera orientation

“controlled”

$$w = k_x \frac{d_x + \ell/2 \sin \phi}{d_z + \ell/2 \cos \phi}$$

Size of individual characters

$$c = f(k_x, d_x, d_z, \phi; \text{position on label})$$

# Obtaining an OCR-ready image

- Positioning of Camera(s)
  - multiple labels in one image
  - high quality image of all labels
    - minimize perspective distortion
    - characters scaled for successful OCR

- Image processing
  - Clean up
  - Alignment
  - Composite image from multiple views

# Can we re-align?

## Camera Images

## Re-Aligned

# Can we make a composite or use just pieces of each?

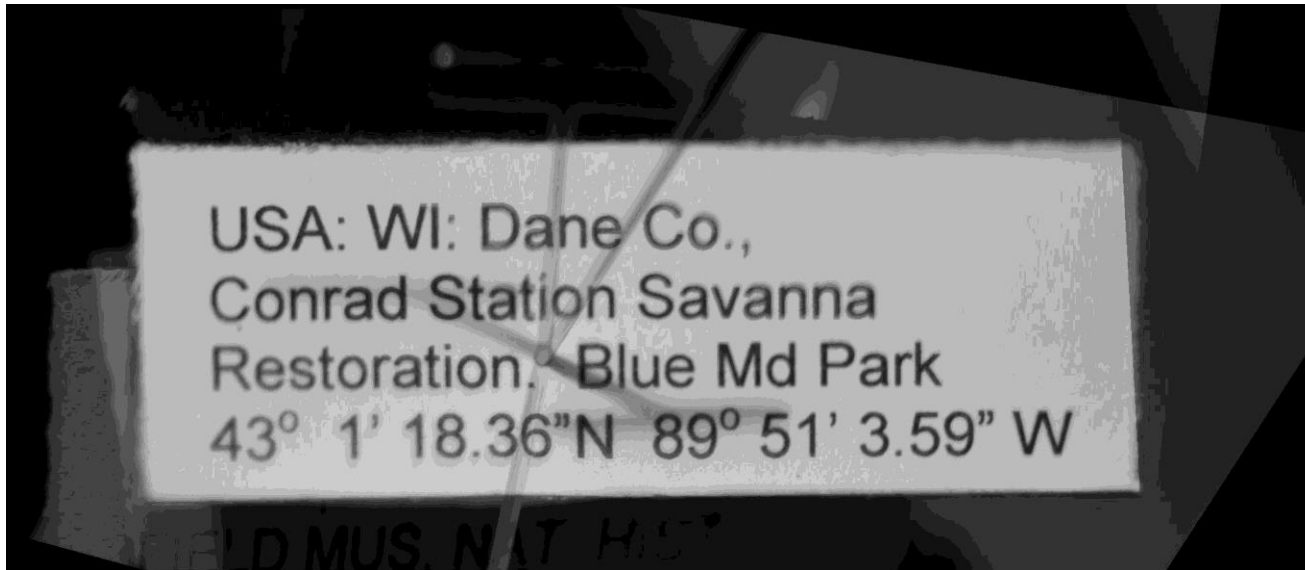

# Composite Image

## via registration & averaging

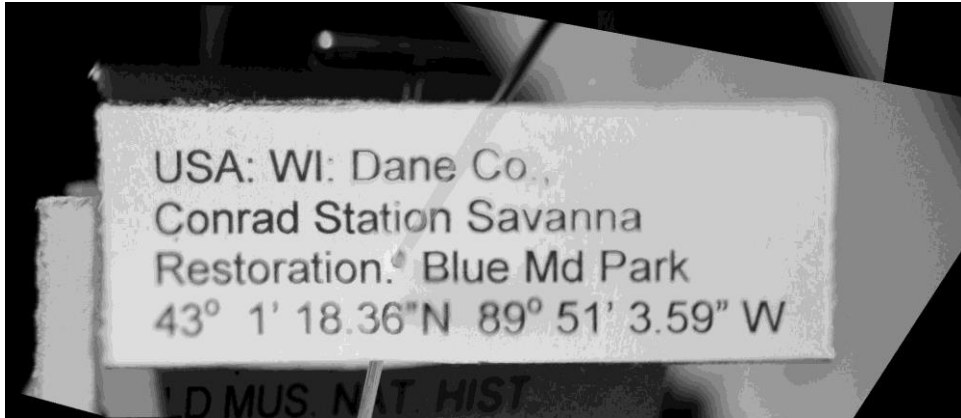

- Used “best in class” registration to automatically align images
- Average pixels from all aligned images

Does not adjust for:

- Poor quality (i.e. out of focus pixels)
- Obstructions (e.g. pin)

# Winner take all

One pixel selected from each image based on:

- 1) Max value
- 2) Min value
- 3) median value

Future: Need to consider other methods – e.g. Pixel “quality” measure?

# Try in-painting?

USA: WI: Dane Co.,  
Conrad Station Savanna  
Restoration. Blue Md Park  
43° 1' 18.35"N 89° 51' 3.59" W

- Need a decent mask
- Doesn't seem to be an improvement over simpler methods

# A Label Automation Flowchart

Tesseract OCR timing test: 1000 characters per second

Data storage: in TBs range

# Label Automation

- OCR may be feasible solution
  - Train & improve performance
- Need to collect high quality images
  - Enough resolution for successful OCR
  - Handle occlusion, poor focus, distortion
- Computation (OCR, possibly improved image processing) is not a bottleneck
