

Insect Soups: Enabling access to an underutilised and valuable resource?

Paul Flemons

November 2013

nature culture **discover**

What is Insect Soup?

- Samples of insects collected through bulk/indiscriminate sampling techniques:
 - Malaise traps, pitfall traps, flight intercept traps, berlese funnels, etc.
- Benefits:
 - Large samples of broad range of taxa from one point over time.
 - Targets specimens not easily captured by other means (active searches, light traps etc.).
 - Passive capture, i.e. can be set and left.

What is Insect Soup?

- **Storage:**

- Jars or tubes of ethanol.
- Some sorted into ordinal groups (e.g. Coleoptera, Diptera etc.).
- Many are mixed lots.

- **What we always know:**

- Where and when the sample was collected.
- Who collected the sample.
- Where the vial is physically located in the collection.

What is Insect Soup?

- What we often don't know:
 - What's in them.
 - Taxa?
 - No. of specimens?
 - What was in them, and is now not in them (i.e. specimens removed from sample).

Without this information, it makes it extremely difficult for researchers to evaluate whether or not a particular bulk sample is useful.

Why is Insect Soup useful?

- Insect soup is a source of real and potential data for:
 - discovering new species,
 - extensions of species distributions /ranges
 - eg pest species
 - statistics on ecological patterns and measures of biodiversity richness and diversity,
 - record of taxa used in eco-genomics analyses
 - time series analysis
- This data has application in :
 - land use and conservation planning
 - quarantine and pest species management
 - climate change research
 - disease vector analysis
 - etc

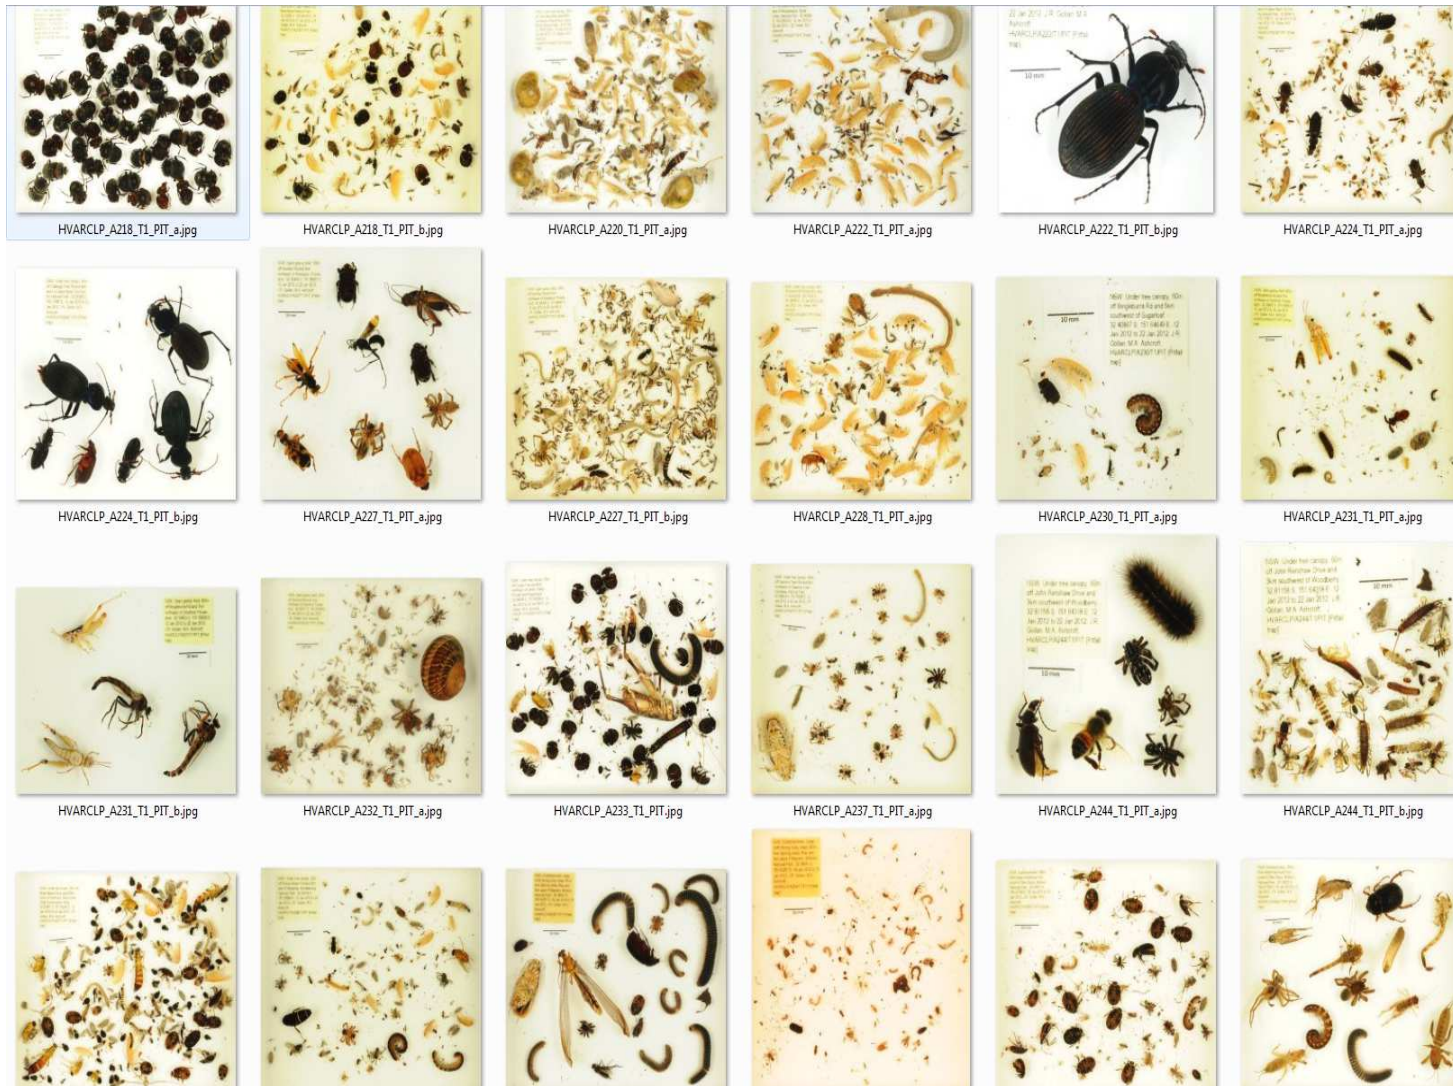

Making our Insect Soups Accessible and useful to Science

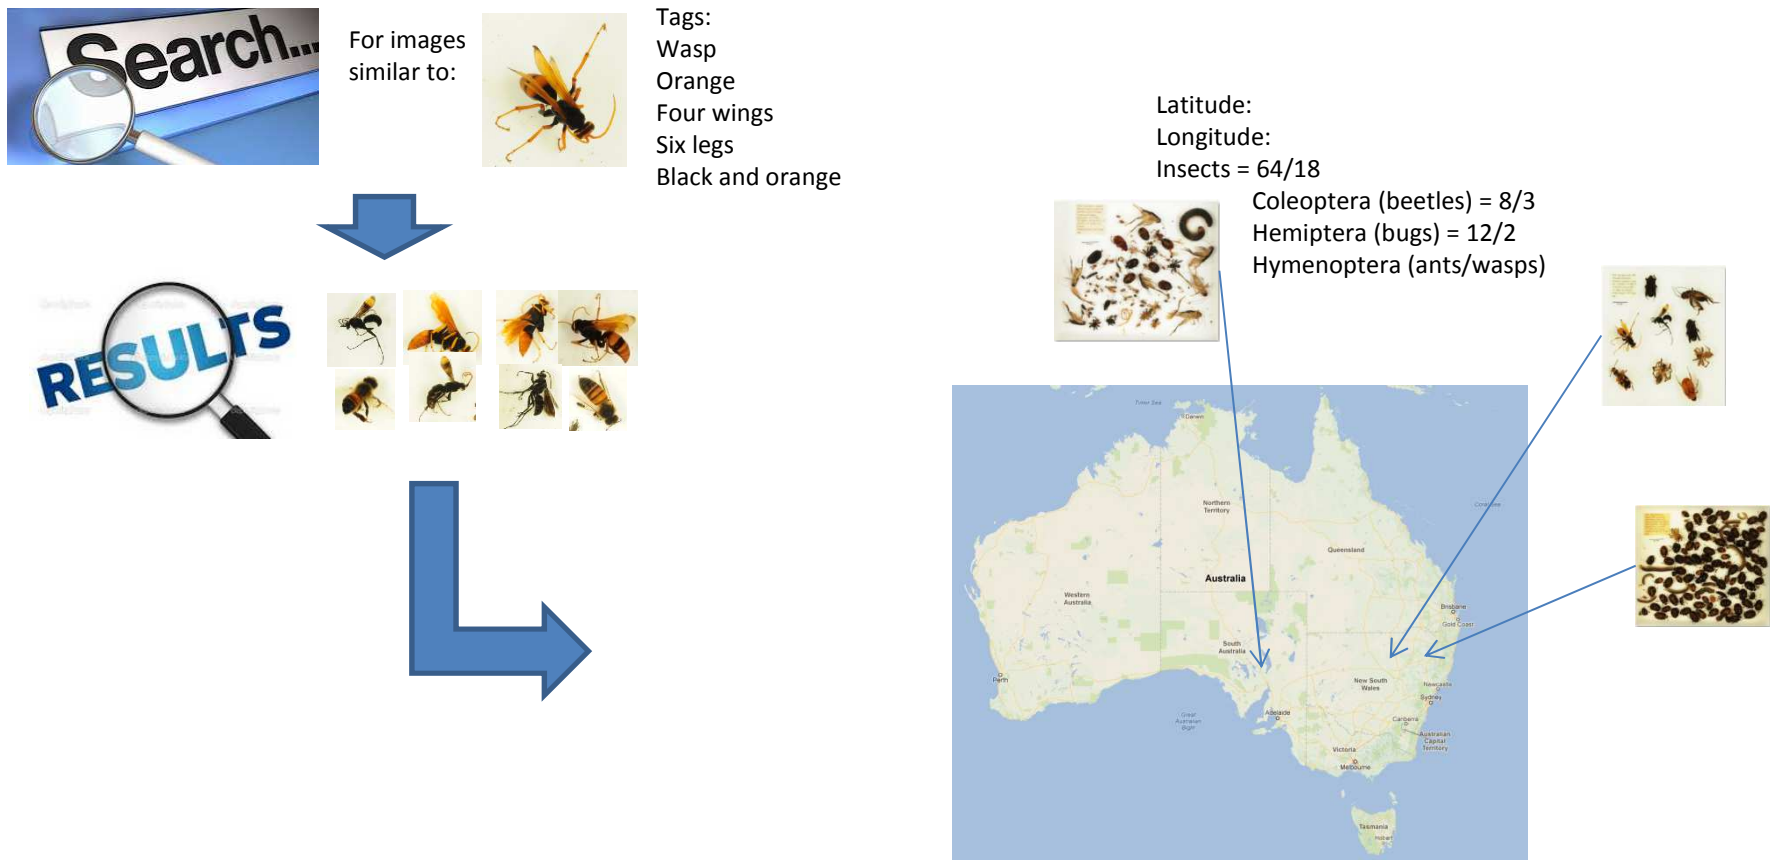

Step 1: Photograph Soups

Patterns immediately obvious

Step 3: Build website tools for researchers to explore the images: for new species, extensions of species distributions and the statistics for ecological patterns, and taxa used in eco-genomics analyses.

Result:

Cost effective way of researching insect richness and diversity by making the most of our existing collections

Nature **448**, 692-695 (9 August 2007) | doi:10.1038/nature06021; Received 20 April 2007; Accepted 14 June 2007

The search results grid displays various images related to the query 'striped abdomen'. The top row features two large images of wasps, a diagram of a honey bee with labels, a spider, and several smaller images of insects and cartoon ants. The second row includes images of a fly, a beetle, a spider, a person's waist in striped underwear, a scorpion, a shoe with a striped sole, a caterpillar, and a sparrow. The third row shows a fly, a sparrow, a shoe with a striped sole, a scorpion, a cat, and two illustrations of a woman's torso with a striped pattern.

Measures of

- richness
- abundance

The Insect Soup Challenge

Goals

Computer vision techniques are to be used to extract meaning from the imagery by categorising and reporting on specimen qualities such as:

- Colour, Size, Shape, and/or Wing Venation
- Location (via bounding box or colour mask)
- Grouping of specimens within an image into like groups approximating:
 - Taxonomic Orders eg Hymenoptera, Diptera
 - Morphospecies[See Bioscience Resources section below for further information]
- Counts of:
 - Overall number of specimens in an image
 - Diversity of groups in an image, for example:
 - Of Orders – number of different Orders in an image
 - Of morphospecies – number of different morphospecies in an image
- Abundance within each group in an image, for example:
 - Number of individual specimens in each order in an image
 - Number of individual specimens in each morphospecies in an image
- Similarity measures within groups
- Outliers
