

Digital palynology: imaging, automation, and intelligent databases

Surangi W. Punyasena

University of Illinois, Urbana-Champaign
Plant Biology, Geology, Geography,
Informatics

punyasena@life.illinois.edu

Digitization and databasing effort
is significant.

Databases require active curation.

Existing image databases (exclusively?)
employ text-based search
based on manual, expert tags

Are there alternative models for approaching visual specimen data?

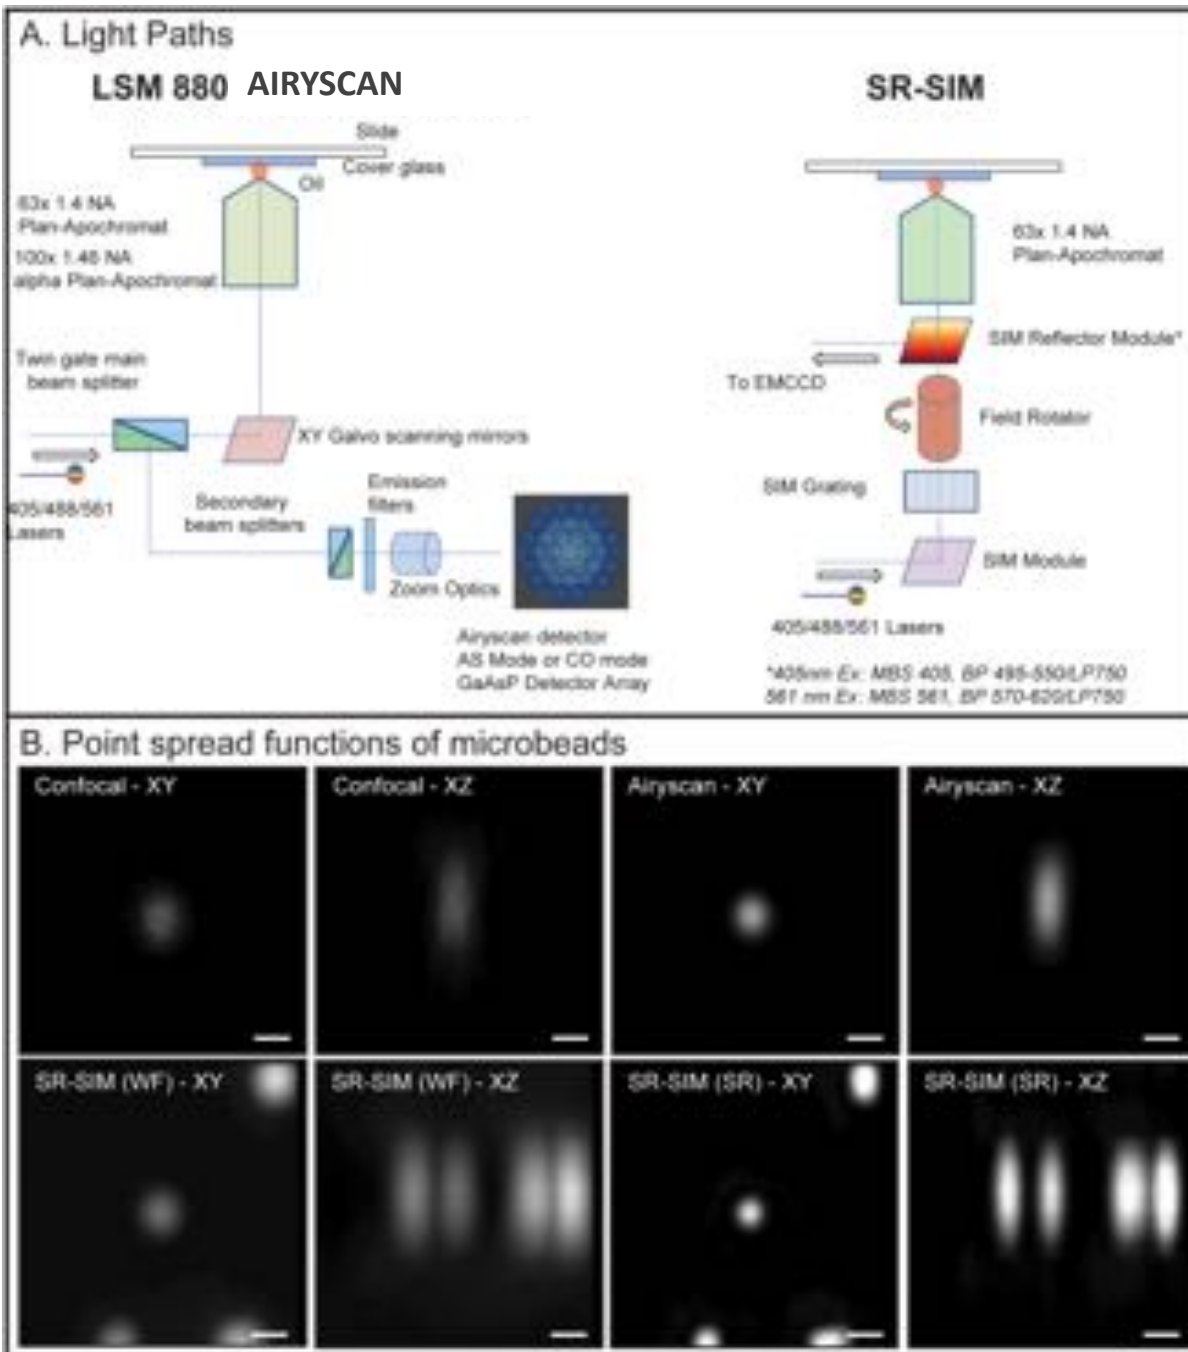

HANDLING VISUAL (MICROSCOPIC) DATA

- Increase throughput of microscopic imaging
 - Adapting existing slide scanning microscopes to pollen specimen slides
 - Purpose-built software to work with microscope APIs/image documentation
- Improve resolution of imaging
 - Archival images must capture the same visual information evident on a (diffraction-limited) microscope or better
- Automate “knowledge capture”
 - Archives must efficiently record and efficiently transfer expert knowledge
 - Utilize computer vision/machine learning

RECONSTRUCTING PALEO-POPULATION DYNAMICS

Anderson Pond, TN

Cupola Pond, MO

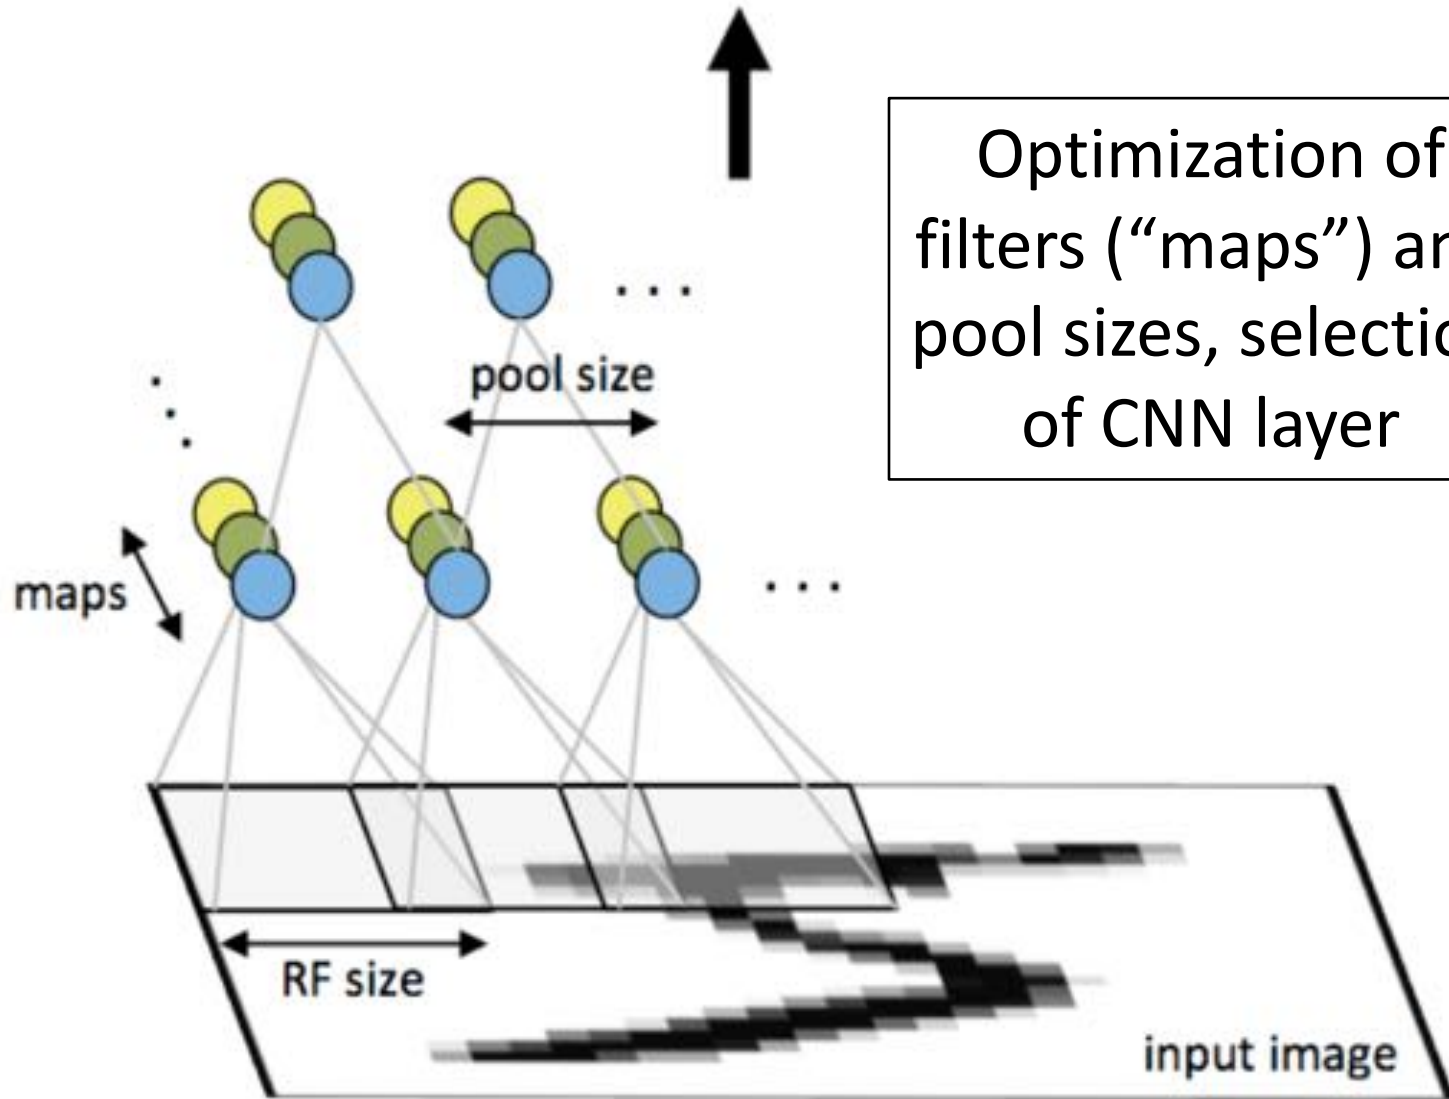

Morphometric approaches only allow us to classify grains in a specific orientation.

Collaborators at UC Irvine, Computer Science (Shu Kong and Charles Fowlkes) experimented with “deep learning” convolution neural nets as an alternative.

Created a set of overlapping patches (52 x 52 pixels)

Patch features were learned using a CNN (VGGVeryDeep-19) model that created an output of hidden layers (512-dimensional vectors) that were used as our classifiers.

Optimization of filters (“maps”) and pool sizes, selection of CNN layer

Used k -medoids clustering of downsized images to identify canonical shapes. Only two representations were necessary: equatorial and polar views.

Images were rotated to match canonical shapes.

MODERN REFERENCE

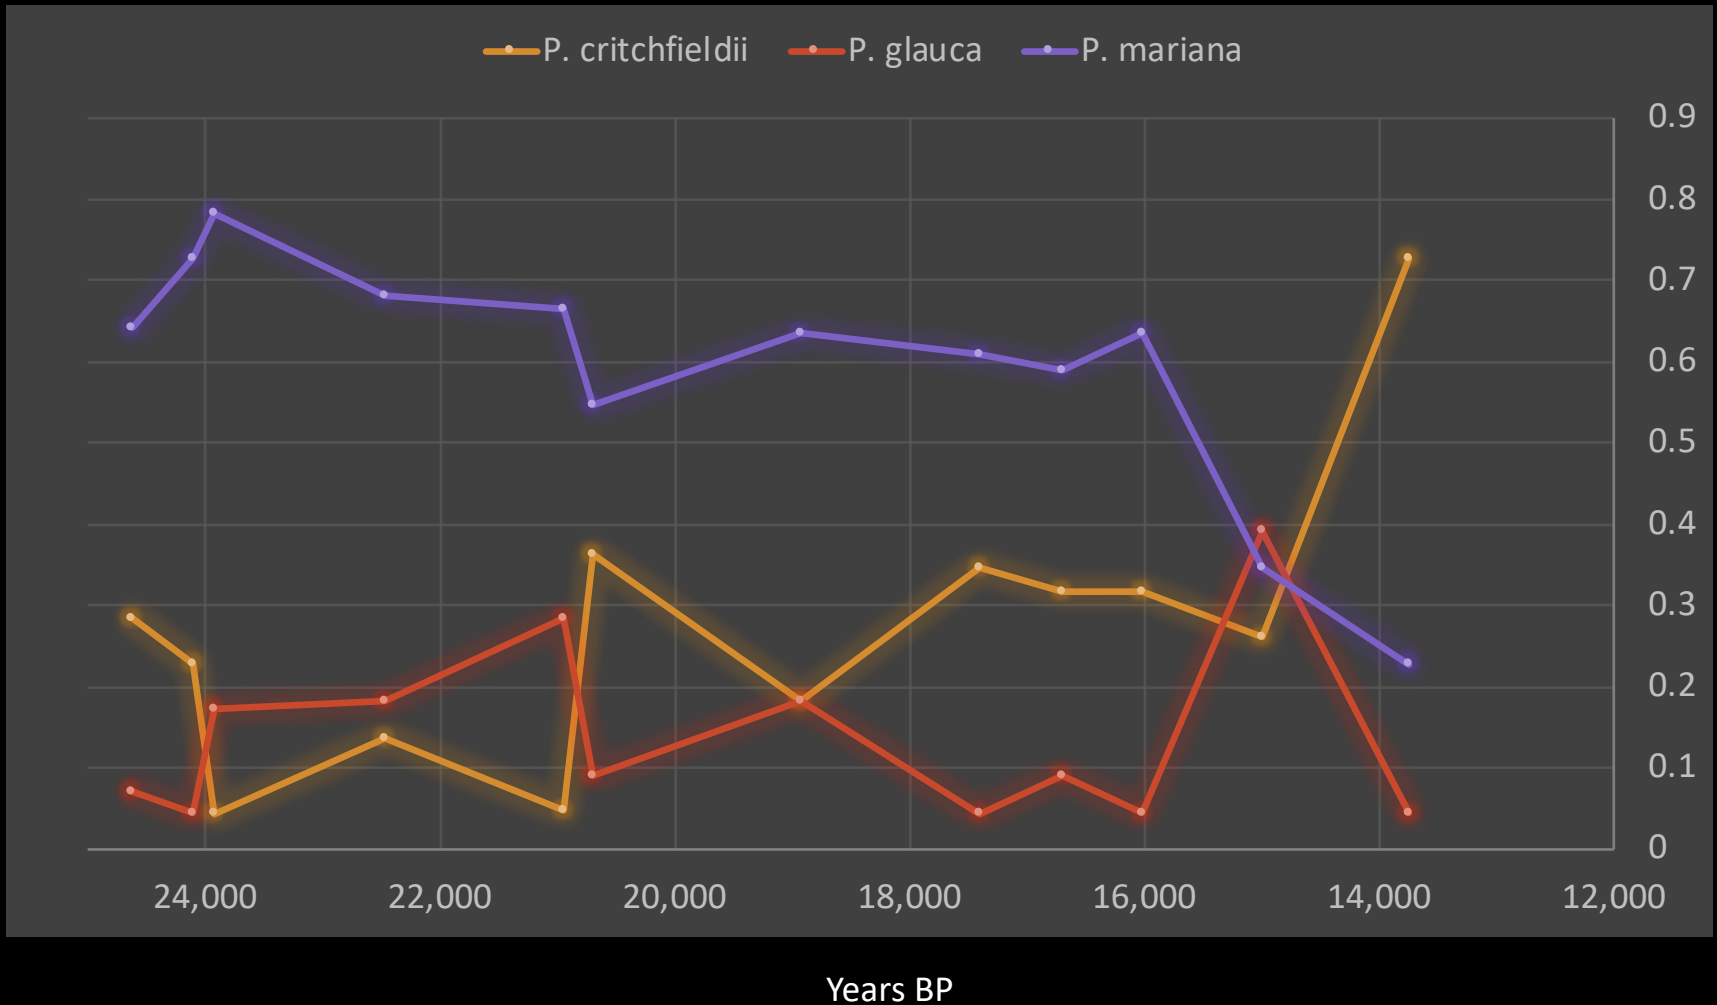

FOSSIL

System was trained on reference material
and used to classify fossil samples.

70% accuracy (no published attempt can replicate)

A PRELIMINARY APPLICATION

Anderson Pond, TN

HANDLING VISUAL (MICROSCOPIC) DATA

- Many of the technologies needed to do this work well (advanced microscopy, slide scanners, computer vision algorithms) already exist.
- Applicable to a range of microfossil (and macrofossil) datatypes.
- Potential to streamline data capture and analysis and improve our science (new hypotheses could be tested, more ambitious research performed)
- As a community, we should apply these tools to our work (and not fear that we are relinquishing our expertise)

Late Quaternary extinction of a tree species in eastern North America

Stephen T. Jackson* and Chengyu Weng†

Department of Botany, University of Wyoming, Laramie, WY 82071

Edited by Margaret Bryan Davis, University of Minnesota, St. Paul, MN, and approved September 27, 1999 (received for review July 8, 1999)

Proceedings of the National Academy of Sciences 1999

HYPOTHESES FOR EXTINCTION

A Species distributions with climate

B Distribution shifts with climate change

C Declining habitat size

D Migration barrier

E Limited dispersal ability

F Critical unknowns

“Southeastern” *sensu lato* localities with >1%
Late Pleistocene/Holocene spruce pollen
